

Meridian Network Access Policy (v3, 2024)

Zones and reachability

Production is divided into four zones: edge (public-facing proxies and the rate limiter), service (application workloads), data (Postgres, Redis, queues), and ops (bastion, CI runners, observability). Traffic flows edge -> service -> data; nothing in the data zone accepts connections from the edge zone directly.

The replication VLAN between db-primary-2, db-replica-1, and db-standby-3 is isolated from all four zones; only WAL traffic and pg_basebackup are permitted (see: Postgres HA architecture review).

All human access enters through the bastion with short-lived certificates minted by Vault; direct SSH to production hosts is denied by security group. Emergency break-glass access requires two approvers and auto-expires in 60 minutes.

Meridian Network Access Policy (v3, 2024)

Change control

Security-group and firewall changes ride the same pipeline as code: proposed in a PR, applied by CI, never edited in a console. Console drift is detected nightly and auto-reverted, with a page to the platform on-call.

Each quarter the SOC2 access review (see: SOC2 quarterly access review procedure) reconciles zone rules against the service inventory; rules that reference a service not in the inventory are removed by default.
